**KEY WORDS:** Simulated Annealing Algorithm, Genetic Algorithm, Particle Swarm Optimization, Optimal TLS Network Design

## ABSTRACT:

The optimal network design problem has been well addressed in geodesy and photogrammetry but has not received the same attention for terrestrial laser scanner (TLS) networks. The goal of this research is to develop a complete design system that can automatically provide an optimal plan for high-accuracy, large-volume scanning networks. The aim in this paper is to use three heuristic optimization methods, simulated annealing (SA), genetic algorithm (GA) and particle swarm optimization (PSO), to solve the first-order design (FOD) problem for a small-volume indoor network and make a comparison of their performances. The room is simplified as discretized wall segments and possible viewpoints. Each possible viewpoint is evaluated with a score table representing the wall segments visible from each viewpoint based on scanning geometry constraints. The goal is to find a minimum number of viewpoints that can obtain complete coverage of all wall segments with a minimal sum of incidence angles. The different methods have been implemented and compared in terms of the quality of the solutions, runtime and repeatability. The experiment environment was simulated from a room located on University of Calgary campus where multiple scans are required due to occlusions from interior walls. The results obtained in this research show that PSO and GA provide similar solutions while SA doesn't guarantee an optimal solution within limited iterations. Overall, GA is considered as the best choice for this problem based on its capability of providing an optimal solution and fewer parameters to tune.

## 1. INTRODUCTION

Unlike methods that only capture specific individual points at a time, e.g., a total station or GPS, light detection and ranging (LiDAR) systems measure large amounts of 3D points with very high acquisition speed. TLS quickly captures rich detail of an entire scene like a camera taking a 360° photo but with an accurate 3D position for every pixel. It determines the object position based on the time-of-flight or phase-shift between the laser beam emitted to the object and the corresponding reflected signal. In other words, TLS provides a remote sensing surveying technique with high speed, density, and accuracy, which makes it widely used in various fields within recent decades such as: 1. Engineering surveying, as topographical surveying (Lague et al., 2013), civil engineering surveying (Oskouie et al., 2016), deformation monitoring (Mukupa et al., 2016), and complex industrial equipment modelling (Son, 2014); 2. Architecture reconstruction (Santagati et al., 2013), heritage documentation and preservation (Fanti et al., 2013); 3. Environmental monitoring and disaster prevention (Abellán et al., 2014). Since the objects to be scanned are either large (e.g., a very tall building) or occluded/self-occluded (e.g., a complex industrial site), a scanning network consisting of multiple scan locations is usually required to provide complete coverage of the object, which is the focus of this paper.

The network design problem has been proposed and well addressed in geodesy (Kuang, 1996; Schmitt, 1982) and non-topographic photogrammetry (Fraser, 1982, 1984). Based on the widely-accepted classification proposed by Grafarend (1974), the network design problems can be divided into four interrelated

sub-problems. They are: zero-order design (ZOD), which is to define a datum for the network; first-order design (FOD), which is to determine a configuration of instruments provided the stochastic model for observations is known; second-order design (SOD), the purpose of which is to optimize the stochastic model for observations; and, finally, third-order design (TOD), which is about further improvement to the network. The FOD of an indoor TLS network is of concern here, since only the distribution of scans is to be designed. Furthermore, the scans will be registered with signalized targets, then the overlap between adjacent scans need to be incorporated as well (Wujanz and Neitzel, 2016).

Different configurations of TLS network impact the precision of TLS observations, the performance of registration, and eventually the quality of the final product. Over the past 15 years, several research papers and articles have appeared concerning this topic. Much research has demonstrated that scanning geometry impacts TLS observation quality. According to Soudarissanane et al. (2011), the scanning geometry of the laser beam is defined as the incidence angle between the laser beam and the object, as well as the range between the scanner and the object. Overall, from existing research it can be concluded that the quality of range observations decreases with increasing incidence angle (Lichti, 2007; Pejic, 2013; Roca-Pardiñas et al., 2014; Soudarissanane et al., 2011; Ye and Borenstein, 2002) as well as scanner-object range (Boehler et al., 2003; Pejic, 2013; Roca-Pardiñas et al., 2014; Soudarissanane et al., 2011; Ye and Borenstein, 2002). The configuration of targets also need to be considered for registration using targets. Generally speaking, at least three targets should be evenly distributed throughout the scan overlap region (Becerik-Gerber et al., 2011; Johnson and

\* Corresponding author

Johnson, 2012). It also has demonstrated numerically that the targets should not be bunched together, collinear or near collinear (Gordon and Lichti, 2004).

A significant topic in the network design problem is network optimization. It can be said that optimal network design problems have been considered by surveyors ever since their inception, when most networks were designed based on surveyors' intuition or experience. With the development of modern computer technologies, the design approaches have evolved from the empirical methods (Asplund, 1963), through analytical methods (Kuang, 1996; Schmitt, 1985a and 1985b), to some well-known heuristic methods, e.g., simulated annealing (Baselga, 2011; Metropolis et al., 1953), genetic algorithms (Holland, 1975; Saleh et al., 2004), and particle swarm optimization (Doma and Sedeek, 2014; Kennedy, 2011), whose principles are inspired by many adaptive optimization phenomena in nature.

An optimal network design with maximum quality and minimum cost is necessary, especially when the network volume is large, like a scanning network consists of thousands of scans (e.g., Hullo, 2016), which is the major motivation of this study. The subject of this paper is to solve the FOD problem using three well-known heuristic methods, SA, GA and PSO, and make a comparison of their performances on an indoor TLS network example. As a starting point of TLS network design, the example and methods applied in this paper will eventually be extended into more realistic and complicated networks.

This paper is structured as follows: the background of network design problems and the literature review for TLS network design are provided in this section. Three heuristic methods used in this paper are introduced in Section 2 while the optimization problem to be solved is described in Section 3. Performances of three optimization methodologies on a simulated indoor TLS network are compared in Section 4 and finally, conclusions are presented in Section 5.

## 2. HEURISTIC METHODS INTRODUCTION

### 2.1 Network Optimization Procedures

The general procedures for optimal network design can be summarized as follows (Kuang, 1996):

- Step 1: Defining network quality criteria
- Step 2: Determining the initial network design
- Step 3: Solving for the optimal network design solution

Before network design, a quality measure must be determined for optimization. This quality measure is represented by an objective function  $f(x)$  depending on a set of parameters  $x$  within the search domain  $D$  and subjected to certain constraints,  $C_i$ . To search for the optimum, the problem is formulated as:

$$\begin{aligned} & \min f(x) \quad x \in D \\ & \text{Subject to: } C_1, C_2, \dots, C_i \end{aligned} \quad (1)$$

Techniques for the optimization of the problem in Eq. (1) can be classified as analytical methods and heuristic methods. The concept of analytical methods is to construct and minimize the objective functions  $f(x)$  under the proposed constraints. This minimization is usually realized by using Taylor series expansion to linearize the non-linear functions with respect to design parameters (e.g., scanner locations in TLS network). Analytical methods can automatically produce an optimal solution that

meets the pre-set quality requirements. In recent decades, some heuristic methods based on simulating the mechanism of the natural ecosystem have been proposed and studied to solve the complex large-scale optimization problems.

Analytical methods are computationally efficient while the heuristic methods avoid the derivation of complicated mathematical equations. This paper focuses on the comparison of three heuristic methods in the FOD of indoor TLS network optimization, whose principles will be introduced below.

### 2.2 Simulated Annealing Algorithm

The simulated annealing method was first developed by Metropolis et al. (1953). It simulates the rearrangement of particles in a body to crystalline state accompanied by the decrease of temperature. The particles of a body move freely within a range with an amplitude determined by the body temperature. Provided the cooling is slow enough, the particles can arrange themselves in states of increasingly lower energy, leading eventually to the state of lowest energy, i.e., the crystalline state (Baselga, 2011). The idea of SA follow the Monte-Carlo iterative method (Berne, 2004):

- 1) Initial solution  $x_0$ . An arbitrary initial solution  $x_0$  and its objective function  $f(x_0)$  are generated. In this paper,  $x$  represents a scanning plan with a set of scanner locations,  $f(x)$  is the quality of this scanning plan, which will be further clarified in subsection 3.3.
- 2) Improvement  $\Delta x$ . The improvement  $\Delta x$  is generated by a random distribution function, which reflects the free movement of the particles. One of the most suitable functions is the normal distribution with density function of:

$$g(x) = \frac{1}{\sqrt{2\pi}\sigma_i} e^{-\frac{x^2}{2\sigma_i^2}} \quad (2)$$

where  $\sigma_i$  is the standard deviation that defines the movement amplitude in each iteration and is determined by the current temperature  $T(i)$ :

$$\sigma_i = \sigma_0 \beta^{T(i)-1}, \quad 0 < \beta < 1 \quad (3)$$

where  $\sigma_0$  = the initial standard deviation  
 $\beta$  = the cooling factor

For the temperature in each iteration, some widely accepted cooling schemes are (Baselga, 2011):

$$\begin{aligned} T(i) &= \frac{T_0}{\log(i+1)} \\ T(i) &= \frac{T_0}{1+i} \\ T(i) &= T_0 \alpha^i, \quad 0 < \alpha < 1 \end{aligned} \quad (4)$$

where  $T_0$  = sufficiently high initial temperature, e.g., 10000°C, so the particles move widely in the body  
 $\alpha$  = cooling rate

For the application in this paper,  $\sigma_0$  is determined based on the size of the room so that the candidate solutions can move freely within the entire room. The initial temperature  $T_0$  and cooling factors  $\alpha$  and  $\beta$  are empirical values that largely effect the algorithm performance.  $\beta$  is usually set as  $\alpha^2$  to reduce the undefined parameters.

- 3) Acceptance criteria Equation 5 is used to prevent the solution from falling into a local minimum.

$$x_{i+1} = \begin{cases} x_i + \Delta x & \text{if } f(x_i + \Delta x) < f(x_i) \\ x_i + \Delta x & \text{otherwise with a probability } p \\ 0 & \text{otherwise} \end{cases} \quad (5)$$

where

$$p = e^{-\frac{f(x_i + \Delta x) - f(x_i)}{T(i)}} \quad (6)$$

- 4) Repeat step 2 and 3 until the stop criterion is reached. In this paper, the stop criterion for all methods is the maximum number of iterations. Then the solution with the minimum objective function is save as the optimal network design.

The flowchart in Figure 1 shows the simulated annealing method.

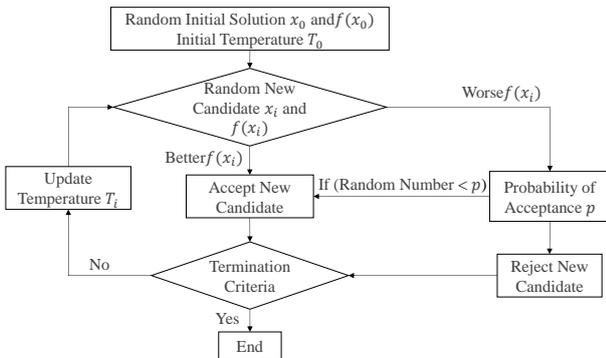

Figure 1. Flowchart of the simulated annealing method

### 2.3 Genetic Algorithm

Developed originally by Holland (1975), the genetic algorithm is based on Darwinian evolutionary theory of survival of the fittest. A new population (i.e., a group of candidate solutions) is generated from old ones based on some genetic rules. Each solution is evaluated by its fitness until the best solution is found. The basic principle of GA is outlined as follows:

- 1) Initial population. Generate a random population with  $i$  chromosomes,  $x_0^i$ , and their objective functions,  $f(x_0^i)$ . The chromosomes  $x^i$  in this paper are  $i$  scanning plans with different sets of scanner locations and  $f(x^i)$  represent the quality of each plan.
- 2) Generate a new population. A new population is created based on Darwinian evolutionary theory with three genetic operators as shown in Figure 2:
  - Selection: Select two chromosomes from a population with a probability based on their objective functions;
  - Crossover: Elements of two parent chromosomes are crossed over based on a certain rule to create two children chromosomes;
  - Mutation: Elements in an arbitrary chromosome is mutated with a mutation probability.

These three operations are repeated until each chromosome in the population have been modified (i.e., a new population is generated).

Population	Chromosome 1	1	0	0	1	1	1
	Chromosome 2	0	1	1	0	1	0
	Chromosome 3	1	0	1	1	0	1
	...	1	0	0	0	1	0
	Chromosome n	0	0	1	1	1	1
Crossover	Chromosome 1	1	0	0	1	1	1
	Chromosome 2	0	1	1	0	1	0
	Chromosome 1	1	0	1	1	1	1
	Chromosome 2	0	1	0	0	1	0
Mutation	Chromosome 3	1	0	1	1	0	1
	Chromosome 3	1	0	1	0	0	1

Figure 2. Illustration of the GA operators

- 3) Keep generating new population until the stop criterion is reached and the chromosome with the minimum objective function is considered as the optima.

Flowchart of the Genetic Algorithm is depicted in Figure 3:

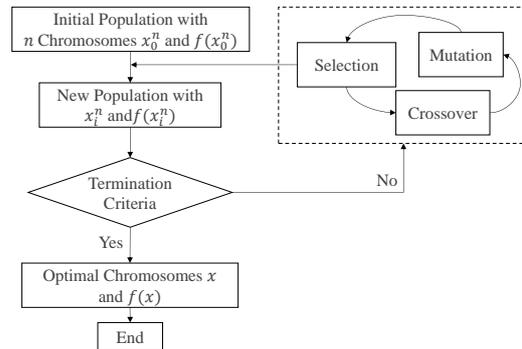

Figure 3. Flowchart of the genetic algorithm

### 2.4 Particle Swarm Optimization

The particle swarm optimization (Kennedy, 2011) is based on the movement of a group of birds (i.e., particles). Each particle flies in a defined search space to discover its best solution, and adjusts its movement based on its own flying experience as well as the flying experience of other particles (Doma and Sedeek, 2014). The PSO algorithm has four main steps:

- 1) Initial particles. Generate  $i$  particles with random positions  $x_0^i$  within the search domain  $D$ , random velocities  $v_0^i$  and objective functions  $f(x_0^i)$ . Similar to GA, particles  $x^i$  are  $i$  scanning plans with different sets of scanner locations, and  $f(x^i)$  are the quality of each plan.
- 2) Velocity update. The velocity of each particle  $v_k^i$  is updated based on the local optimum position  $p^i$  of this particle over time, and the optima of all particles  $p^g$ :

$$v_{k+1}^i = wv_k^i + c_1 rand \frac{(p^i - x_k^i)}{\Delta t} + c_2 rand \frac{(p^g - x_k^i)}{\Delta t} \quad (7)$$

where  $w$  = inertial factor  
 $c_1$  = self-confidence factor  
 $c_2$  = swarm confidence factor

The first two terms represent the influence of current motion and previous optimal motions of this particle; the third term is the influence of the optimal motion of all particles. Factors  $w$ ,  $c_1$  and  $c_2$  are empirical values that largely effect the algorithm performance.

- 3) Position update. The positions are updated based on their velocities with Equation 8:

$$x_{k+1}^i = x_k^i + v_{k+1}^i \Delta t \quad (8)$$

The idea of PSO algorithm is depicted in Figure 4:

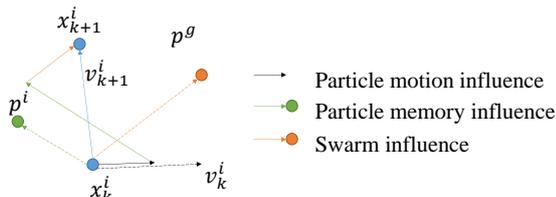

Figure 4. Position update in PSO algorithm

- 4) Termination criterion. Step 2 and 3 are repeated until the stop criterion is met. Finally, the position with the minimum object function will be saved as the optimal solution.

The flowchart of the PSO method is shown in Figure 5:

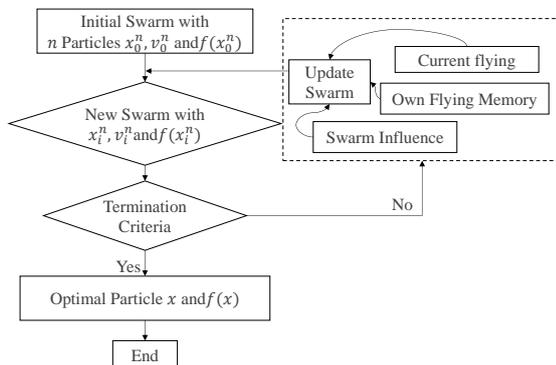

Figure 5. Flowchart of the particle swarm optimization

### 2.5 Parameters Description

The adopted parameters in each heuristic method for the network design problem in this paper are clarified in Table 1:

Unknown parameters $x$		A set of scanner locations
Objective function $f(x)$		Summation of incidence angles (explained in subsection 3.3)
Empirical parameters	SA	Initial temperature: $T_0$ Initial standard deviation: $\sigma_0$ Cooling factors: $\alpha$
	PSO	Inertial factor: $w$ Self-confidence factor: $c_1$ Swarm confidence factor: $c_2$
	GA	—

Table 1. Adopted parameters in the three heuristic methods

### 3. OPTIMIZATION PROBLEM

The problem of interest in this paper is the optimal design of an indoor TLS network using the three heuristic methods. The optimization problem is stated as: minimize the number of necessary scanner locations to obtain full coverage of an indoor scene. This network optimization is solved based on (Soudarissanane and Lindenbergh, 2011):

- 1) The 2D map of a scanning scene;
- 2) The discretized scanning scene;
- 3) The discretized possible viewpoints (VPs).

In the work of Soudarissanane and Lindenbergh (2011), the optimal solution was sought using the greedy algorithm, which is time-efficient but provides sub-optimal solutions. The optimization methods investigated in this paper are relatively time-consuming but find optimal solutions, which can reduce the scanning cost, especially for large networks.

#### 3.1 2D Discretized Data

Figure 6 shows an example of how the data discretization works. The walls of the scanning scene are extracted from the 2D floor map and then discretized with a certain unit (e.g., segments with the length of 1m), as S1 to S8 in Figure 6. Similarly, possible viewpoints are also discretised as VP1 to VP4.

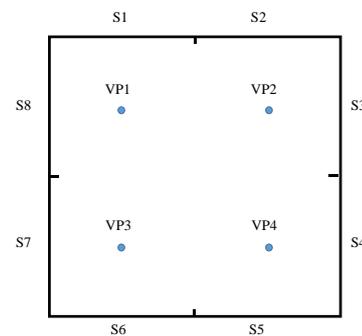

Figure 6. Example of the scanning problem

#### 3.2 Scanning Geometry Constraints

As mentioned in Section 1, TLS observation quality is impacted by scanning geometry. Based on the existing research (Lichti, 2007; Pejic, 2013; Roca-Pardiñas et al., 2014; Soudarissanane et al, 2011), the observation quality is satisfactory when the scanner is placed where:

- The incidence angle of the laser beam is less than  $60^\circ - 65^\circ$ ;
- The range between the object and the scanner is within the range capability defined by the manufacturer.

These two factors are used as constraints in the network design. Since the test data is a small room within the range capability of most scanners, only the incidence angle constraint is considered in this paper. A Boolean score table for all discretised segments from an arbitrary viewpoint is obtained as Figure 7. The visibility zone for one viewpoint is the scanning area where the incidence angle constraint is satisfied. The marking rule is:

- Case 1: Two vertices of the segment fall into the visibility zone;
- Case 0: Less than two vertices of the segment is within the visibility zone.

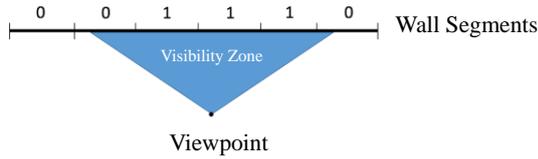

Figure 7. Boolean wall segments

The entire score table for the example in Figure 6 is constructed as Table 2.

Segments \ VP <sub>s</sub>	S1	S2	S3	S4	S5	S6	S7	S8
VP1	1	0	1	1	1	1	0	1
VP2	0	1	1	0	1	1	1	1
VP3	1	1	1	1	0	1	1	0
VP4	1	1	0	1	1	0	1	1

Table 2. Boolean score table for the example in Figure 6

### 3.3 Statement of Problem

It can be seen from Table 2 that the combination of any two and more possible VPs can provide a full coverage of the room. Furthermore, a quality measure needs to be determined for optimization. Since the observation quality is impacted by the incidence angle, the summation of all incidence angles of laser beams hitting the visible segment vertices is defined as the objective function  $f(x)$  in this optimization problem. A small sum of incidence angles corresponds to a network of good quality.

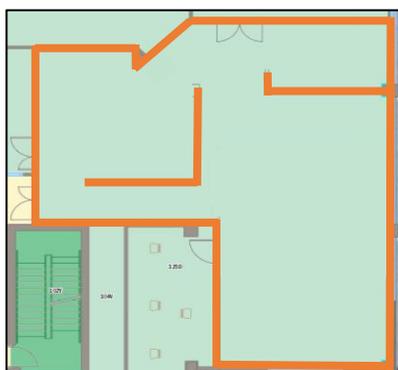

Finally, the optimization problem in this paper is stated as: determine the scanning network using heuristic methods to obtain a full coverage of the indoor scene with minimal number of scan locations as well as minimal summation of incidence angles.

## 4. APPLICATION

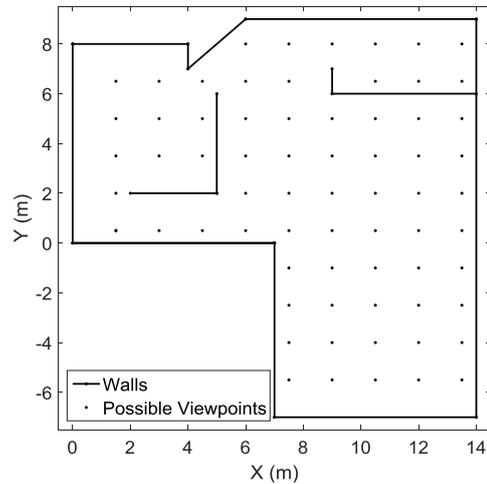

In this section, the SA, GA and PSO methods are used in the problem of optimizing an indoor TLS network design. Each method's performance is compared in terms of the quality of the solutions, runtime and repeatability. All methods are conducted on an Intel® Core™ i5, 3.33GHz, 8 GB RAM computer, in the MATLAB R2015b environment.

### 4.1 Description

**4.1.1 Experiment Environment:** The experiment environment tested in this section is Room 125 in the CCIT building located on the University of Calgary campus. It has an area of 163.96 m<sup>2</sup> and is depicted in Figure 8(a).

(a) 2D floor map

(b) Discretized data

Figure 8. Layout of the experiment data

With the known coordinates of the room corners, the walls were extracted as shown in Figure 8(b). Using the method described in Subsection 3.1, the room was discretized into 74 wall segments with length of 1m and 68 possible viewpoints with an interval of 1.5m.

**4.1.2 Pseudocode:** Table 3 shows the pseudocode of the method used in the experiments. The room is discretized as wall segments  $S_i$  and possible viewpoints  $VP_j$  with their score tables  $ST_j$ . The method starts with one arbitrarily-selected viewpoint  $VP_o$ . The location of this viewpoint is updated using SA, GA or PSO and the summation of incidence angles the objective function. Another viewpoint is added into the viewpoints set  $VP_o$  if full coverage cannot be acquired with the current number of viewpoints. The method runs iteratively until a set of viewpoints with full coverage and minimum incidence angle summation is found.

Since the location of viewpoints generated by SA, GA and PSO can be any point bounded by the walls, it is time-consuming to construct a score table for each new viewpoint. To solve this problem, the nearest points of the newly-generated viewpoints are searched in  $VP_j$ . Then their corresponding score tables, which have been pre-generated, can be used directly to improve computation efficiency.

<i>SA, GA and PSO in indoor network design</i>
<b>Input:</b> $S_i, i = 1 \dots m, VP_j, ST_j, j = 1 \dots n$
<b>Output:</b> A set of viewpoints $VP_o \in VP, o = 1 \dots l, l \leq n$ .
Initialization: $VP_o, o = 1$
<b>while</b> $VP_o, o \leq n$
Update $VP_o$ using SA, GA or PSO
Search (the nearest $VP_o$ in $VP_j$ )
tempBest = Min (summation of the incidence angles)
<b>if</b> ~full coverage
Add (one more viewpoint to $VP_o, o = o + 1$ )
<b>else</b>
break
<b>end</b>
<b>end</b>

Table 3. Algorithm pseudocode

**4.1.3 Parameters Selection:** As shown in Table 4, different sets of empirical parameters were tested and their corresponding objective functions were used for evaluation.

Parameters	#VP	Objective function <sup>o</sup> ( $\times 10^4$ )
SA		
$T_0 = 10^4$ , $\sigma_0 = 16m$ , $\alpha = 0.95$	5	1.5670
$T_0 = 10^2$ , $\sigma_0 = 16m$ , $\alpha = 0.95$	6	2.0677
$T_0 = 10^4$ , $\sigma_0 = 5m$ , $\alpha = 0.95$	6	1.9292
$T_0 = 10^4$ , $\sigma_0 = 16m$ , $\alpha = 0.5$	7	2.4493
GA		
—	4	1.3328
PSO		
$w = 0.8$ , $c_1 = 0.1$ , $c_2 = 0.1$	4	1.2536
$w = 0.1$ , $c_1 = 0.8$ , $c_2 = 0.1$	5	1.4396
$w = 0.1$ , $c_1 = 0.1$ , $c_2 = 0.8$	6	1.8069
$w = 0.33$ , $c_1 = 0.33$ , $c_2 = 0.33$	5	1.5474
Maximum iteration: 3000 Number of chromosomes/particles: 30		

Table 4. Parameters selection for each method

As can be seen In Table 4, the performance of each method varied with the selection of parameters. The maximum iterations for all methods was 3000 and the number of chromosomes or particles in GA and PSO was set to 30. No empirical values are required in GA. The parameters to provide optimal solutions for each method are listed in their first rows.

For SA, an extremely large initial temperature  $T_0$ , an initial standard deviation  $\sigma_0$  agrees with the room size and a slow cooling factor  $\alpha$  allow the candidate solutions to move widely within the moving area at first and eventually converge to the optimal solution. Parameters in its first row are proven to provide the optimal solution by varying a single parameter at a time. As in Table 4, tuning the parameters to other values prevents the SA method from finding optimal solutions.

For PSO, the optimal solution can be found when the inertial factor  $w$  is much larger than  $c_1$  and  $c_2$ . By doing so the improvement to the solutions mainly depend on the randomly-generated movement, and are only slightly impacted by the current optimum. If the self-confidence factor  $c_1$  or the swarm confidence factor  $c_2$  is set larger, as in the second and third case in Table 4, the solution is more likely to be stuck in the current optima since the method trusts it too much. Tuning the factors to equal values provide a solution of the medium performance.

## 4.2 Results and Discussion

The performances of three adopted methods are compared regarding the quality of the solutions, runtime, and repeatability.

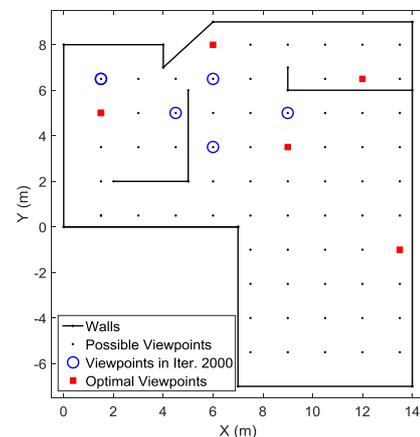

**4.2.1 Quality of the Solutions:** Successive solutions from the three heuristic methods as well as the greedy method are depicted in Figure 9. Represented by different symbols, the optimal solutions from iteration 1000, 2000 and 3000 are green triangles, blue circles and red squares, respectively. Their corresponding objective functions are also provided in Table 5.

It can be seen that within the maximum number of iterations, the performances of PSO and GA are similar. The optimal solution of PSO, i.e., 4 viewpoints with a minimum objective function of

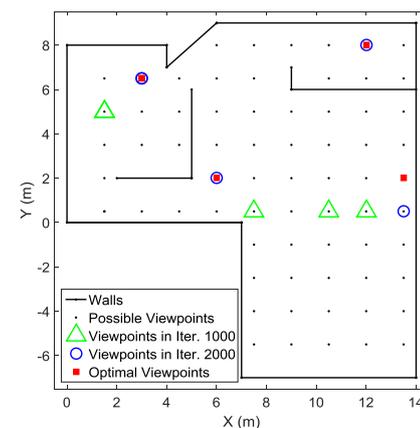

$1.2536 \times 10^4$ , can be found only when the parameter values are suitably selected, which is not an issue for GA. Since SA generates only one candidate per iteration, compared with 30 candidates in GA and PSO, it requires more iterations to find the optimal solution. Thus, SA cannot find a solution for 1000 iterations and only provides a solution with 5 viewpoints within the maximum number of iterations, which can be overcome when the iteration limitation is increased beyond 3000. The greedy method solution shows that a sub-optimal plan with a minimum of 5 viewpoints for this case can be obtained with no iteration, and the impact of being away from the optimum will increase in case of more complex scenes.

Iteration	Successive solutions (Symbols in Figure 9)	Objective function <sup>o</sup> ( $\times 10^4$ )
SA		
1000	—	—
2000	Blue circles (○)	1.7879
3000	Red squares (■)	1.5670
GA		
1000	Green triangles (▲)	1.3416
2000	Blue circles (○)	1.3328
3000	Red squares (■)	1.3328
PSO		
1000	Green triangles (▲)	1.3665
2000	Blue circles (○)	1.3276
3000	Red squares (■)	1.2536
Greedy method		
	Red squares (■)	1.7274

Table 5. Successive solutions and objective functions

(a) SA

(b) GA

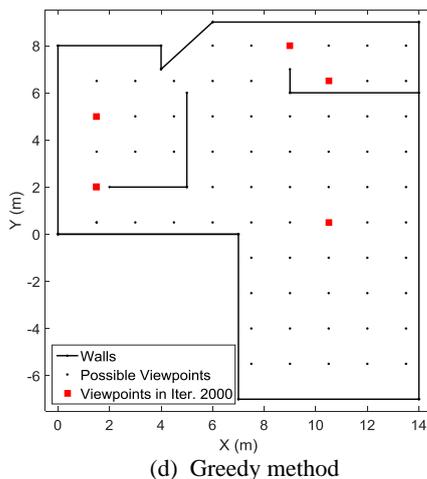

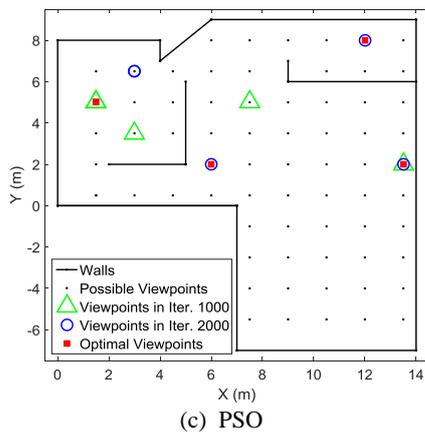

Figure 9. Layout of optimal viewpoints from different methods

**4.2.2 Runtime:** Each optimization method was repeated 20 times and the average runtimes are listed in Table 6. GA and PSO have a similar total runtime and runtime per iteration. The reason that SA runs faster per iteration is because SA generates one solution once per iteration while other two methods generate 30 solutions in each iteration. However, since SA cannot find optimal solutions with 4 viewpoints, its total runtime is longer than the other two methods.

Method	Ave. total runtime	Ave. runtime per iteration
SA	44.3436	0.0074
GA	37.4379	0.0125
PSO	35.5385	0.0118

Table 6. Average runtime

**4.2.3 Repeatability:** The objective functions for the solutions in 20 runs are used to evaluate the repeatability of each method. From Figure 10, one can see that solutions from GA and PSO are more repeatable than solutions from SA, which is demonstrated numerically in Table 7.

Method	Mean	Standard Deviation
SA	$^{\circ}(\times 10^4)$ 1.7828	$^{\circ}(\times 10^2)$ 5.6039
GA	1.3688	1.7252
PSO	1.2784	1.4134

## 5. CONCLUSIONS

Compared with in geodesy and photogrammetry, optimal network design for TLS hasn't received the same attention in current research. In this paper, the first-order design of an indoor TLS network, i.e., the configuration of scanner locations, is of interest. The experiment environment was simulated with discretized wall segments and possible viewpoints. A minimum number of viewpoints with a complete coverage of all wall segments was found by adopting three heuristic optimization methods: simulated annealing, genetic algorithm and particle swarm optimization. The experiment environment was a simulated room located on the University of Calgary campus.

Comparisons were made regarding the quality of the solutions, runtime, and repeatability. It was demonstrated that PSO has the best performance when its empirical parameters are selected suitably while SA performs the worst that cannot guarantee an optimal solution within the same iterations. GA provides similar solutions with PSO with tuning less empirical parameters. Thus, GA is determined as the best choice for this problem.

This problem is currently considered in 2D space, which can be further extended to the more complex 3D problems. Known as the Next Best View problem, this type of problem is normally solved by the strategy of ray-tracing, which is computational complex even for a trivial object (Pito, 1999). Also, constraints like the overlap rate between adjacent scans and the minimum range capability of the selected scanner can be involved. In addition, the number and configuration of targets is another consideration for optimal performance of point cloud registration. Eventually, a full design system that can automatically provide an optimal plan for the high-accuracy and large-volume scanning network is to be developed in this research.
